Report for Breast Cancer

Examination regards uploaded modalities: Mammography, MRI.

[HNH:NH] The breasts appear to contain oncological findings for breast cancer with an abnormal mass or nodule.

[BIR:3] A finding in this category has a very low (no more than 2%) chance of being cancer. It is not expected to change over time. But since it's not proven to be benign, it's helpful to be extra safe and see if the area in question does change over time. Thus, it is recommended to do a follow-up with repeat imaging in 6 to 12 months and regularly after that until the finding is known to be stable (usually at least 2 years).

[DEN:1] In terms of density, breasts are almost all fatty tissue. Almost entirely fatty indicates that the breasts are almost entirely composed of fat.

[STAG:3/4] Breast cancer of this stage means that the cancer has spread from the breast to lymph nodes close to the breast or to the skin of the breast or to the chest wall or the cancer has spread to other parts of the body. This is also called locally advanced breast cancer.

[SEG:UIQ] The cancer appears to be located at the upper inner quadrant of the breast.

Examination sample (DICOM scan):
